Financial Transaction Tax by <i>Gunther Capelle-Blancard</i>	2
A One-Off Wealth Tax to Fund a Sovereign EU Fund by <i>Adrien Fabre</i>	18

Financial Transaction Tax

Gunther Capelle-Blancard

A European financial transaction tax (FTT) is often presented as a politically attractive but technically fragile idea. This is misleading. The proposal considered here is not a utopian attempt to tax global finance in the abstract. It is a pragmatic equity transfer tax, modelled on devices that already exist and operate in major financial markets. The United Kingdom has applied a stamp duty on share transactions for more than three centuries. France introduced its current FTT in 2012, followed by Italy in 2013 and Spain in 2021; beyond Europe, comparable instruments also exist in major financial centres such as Hong Kong and Switzerland, and in around thirty countries worldwide. These examples show that a well-designed FTT can be implemented in open, sophisticated and highly internationalised financial markets without undermining their functioning.

The proposal is to introduce a harmonised EU tax on transfers of ownership of shares issued by companies incorporated in Member States, at a rate of 0.5%, in line with the UK stamp duty.¹ Primary market issuance and genuine market-making activities could remain exempt, as in existing national schemes. The tax would be based on a robust legal and operational design: it would be attached to the security itself, rather than to the location of the broker, the trading venue or the investor. This is the key lesson from existing FTTs: such taxes can work, but only if they are carefully designed so as to limit avoidance and ensure enforceability.

The scope is deliberately narrow. At this stage, the tax would focus only on equities, not because derivatives, foreign-exchange transactions or crypto-assets should remain outside the scope of financial taxation, but because equity transfers provide the most robust and operationally tested base. This also draws a lesson from the earlier European Commission proposal. The 2011–2013 project was much broader: it covered shares, bonds and derivatives, and would have applied to gross transactions before netting and settlement. It was expected to raise much larger revenues, but it also triggered stronger technical and political objections and ultimately failed to secure agreement among Member States. The present proposal therefore does not seek to reopen the full debate on a comprehensive European FTT. It starts with the most feasible component, while leaving broader extensions (in particular the taxation of intraday transactions and other securities transactions) for a later stage.

Under conservative assumptions, the proposed EU equity transfer tax would raise approximately EUR 8 billion per year. The revenue estimate is deliberately prudent. It does not rely on speculative assumptions. Instead, it is anchored in the observed performance of the French FTT in 2024 and then applied to equity trading volumes in other Member States. This approach incorporates, by construction, the existing exemptions, leakages and the narrow effective tax base observed in France, including the exclusion of intraday transactions.

¹The possibility that some new firms might incorporate outside the EU to avoid the tax cannot be entirely ruled out, but it is unlikely to be a major margin of avoidance. The tax would apply only to secondary-market transfers of shares, not to primary issuance, and its rate would be very low relative to the legal, fiscal, regulatory and governance costs associated with incorporating outside the firm's main economic area. For most firms, access to investors, legal certainty, listing conditions and corporate taxation are far more important than a modest tax on future share transactions.

In sum, an EU equity transfer tax would be theoretically grounded, technically feasible, fiscally useful and fair. It would not solve all budgetary challenges, and it should not be oversold. But as one component of a broader package of new own resources, it has a strong comparative advantage: it is based on a tested instrument, it targets a highly concentrated and undertaxed tax base, and even under very conservative assumptions it could generate around EUR 8 billion per year.

The following sections provide the detailed background supporting this proposal. It first presents the rationale and design of the equity transfer tax, before reviewing existing national policies and the earlier European FTT project. They then set out the revenue-estimation methodology and Member State-level results, responds to common objections, review public opinion, and finally discusses possible extensions, notably to intraday transactions.

1 FTT: The rationale

FTTs are neither new nor untested. They have existed for centuries and remain in force in many major financial centres. The most prominent example is the United Kingdom’s stamp duty on share transactions, introduced in the seventeenth century and still applied today to purchases of shares issued by UK companies. Similar taxes are also used in France, Italy, Spain and a number of other jurisdictions such as Switzerland, Singapore, Hong Kong, South Korea, etc. The relevant question is therefore not whether an FTT can exist, but how it should be designed (Capelle-Blancard, 2024a).

The proposal considered here is deliberately simple. It consists in introducing, at EU level, a harmonised tax on transfers of ownership of shares, modelled on existing national schemes such as the UK stamp duty and the French FTT. The tax would apply only to equity transactions, not to bonds, derivatives or foreign-exchange transactions. It would be levied at a rate of 0.5%, in line with the UK stamp duty. The taxable event would be the transfer of ownership; in other words, the proposal does not require taxing all intraday transactions, but focuses on settled net acquisitions of shares. This proposal could serve as a platform for future extensions.

A key design feature is the issuance principle. Under this principle, the tax applies to transactions in shares issued by companies incorporated in the taxing jurisdiction, regardless of the residence or nationality of the investor and regardless of where the transaction takes place. This is the logic underpinning the UK stamp duty and the French FTT. It is crucial for enforceability: the tax is linked to the legal transfer of ownership of securities, not to the location of the trading platform or intermediary. This design considerably limits avoidance opportunities and explains why such taxes can be maintained even in highly internationalised financial markets (Capelle-Blancard and Persaud, 2025).

The economic rationale for an FTT is also well established. Keynes (1936) argued that a tax on transactions could help reduce the excessive dominance of short-term speculation over enterprise. Tobin (1978) later proposed a levy on currency transactions to “throw sand in the wheels” of international finance, while Stiglitz (1989) defended the use of tax policy to curb speculative short-term trading. These arguments differ in scope, but they share a common intuition: when trading is excessively short-term, the private incentives of market participants may diverge from the social usefulness of financial markets. A small transaction cost can therefore serve both as a source of public revenue and as a modest corrective device.

For the purpose of new EU own resources, however, the fiscal argument is central. Existing FTTs are best understood not primarily as instruments of financial repression, but as low-rate taxes on a large and concentrated tax base. Their purpose is to generate revenue from financial market activity

while preserving investment and market functioning. Evidence on the French FTT suggests that the tax reduced trading volumes moderately, by around 10–20%, but without significant effects on market liquidity or volatility (Colliard and Hoffmann, 2017). This is important: the experience of recent European FTTs does not support the view that such taxes are incompatible with deep and efficient financial markets.

The proposal is therefore intentionally pragmatic. Rather than reviving the broader and more politically contentious idea of taxing all financial instruments, it builds on what already exists and works: a narrow, enforceable levy on equity transfers, based on the issuance principle, at a low nominal rate, with standard exemptions for primary issuance and market-making activities where appropriate. This approach would allow the EU to create a new own resource from a tried-and-tested tax instrument, while avoiding many of the objections usually directed at more comprehensive versions of the FTT.

2 Existing national policies

The proposed EU own resource would not be created in a vacuum. Several European countries already tax financial transactions, and the most relevant examples are not marginal cases: they include the United Kingdom, France, Italy and Spain.

The United Kingdom remains the main benchmark. Its stamp duty on share transactions dates back to 1694 and is still in force. It applies at a rate of 0.5% to purchases of shares issued by UK companies. The UK stamp duty raises £4.32 billion in 2024–25, illustrating that such instruments can provide stable and non-negligible revenues. The key feature of the British model is the issuance principle: the tax applies because the share is issued by a UK company, irrespective of the nationality or residence of the investor and irrespective of where the transaction is executed. Primary market issuances, market-making activities and shares listed on the Alternative Investment Market are exempt. The UK experience is particularly important because it shows that a major financial centre can maintain a sizeable equity transaction tax over a very long period without undermining the development of its financial sector.

France introduced its current FTT in 2012. The French tax also follows the issuance principle. It applies to acquisitions of shares issued by companies whose registered office is in France and whose market capitalisation exceeds EUR 1 billion.² The tax is paid by the buyer and it is calculated on net acquisitions recorded at the end of the trading day. This means that the French FTT is not, strictly speaking, a tax on transactions, but a tax on transfers of ownership. Intraday transactions that are opened and closed within the same day are therefore effectively excluded from the tax base.³ The rate of the French FTT was initially 0.2%, then increased to 0.3% in 2017, and 0.4% in 2025. The French case is especially useful for the present proposal because it shows how a modern equity FTT can be implemented unilaterally, even in an open financial market.

Italy introduced a similar tax in 2013, shortly after France. It applies to shares of Italian companies above a market-capitalisation threshold of EUR 500 million. The Italian design is broader in some respects, since it also includes a tax on derivatives and a specific component targeting high-frequency trading. It also differentiates between transactions executed on regulated markets and

²The list of companies subject to the tax is updated annually.

³The French FTT formally has three components: a tax on share transfers, a tax on high-frequency trading, and a tax on naked sovereign credit default swaps. In practice, however, only the first component is effective. The high-frequency trading component is too narrow to generate meaningful revenue, while the naked CDS component became largely irrelevant after EU restrictions on such transactions.

those executed elsewhere: the rate is 0.2% for transactions on regulated markets and 0.4% otherwise (since 2026). This feature is important because it can encourage trading to move towards more transparent and regulated venues. Italy therefore illustrates a possible refinement of the French model, even though the proposal considered here remains focused on a simple equity transfer tax.

Spain reintroduced an FTT in 2021, after having abolished an earlier tax in 1988. The Spanish tax follows the same broad family of instruments as the French and Italian taxes: it focuses on equity transactions and provides another recent example of a Member State implementing an FTT independently. Together, the French, Italian and Spanish cases show that unilateral implementation within the EU is feasible and that such taxes do not require a fully global agreement in order to operate.

Other European countries also have FTTs. Belgium has had a tax on stock-exchange transactions since 1913. Its design, however, differs from the British, French and Italian models. It is linked to the involvement of a Belgian financial institution or to Belgian-resident investors, and it appears easier to circumvent than systems based on the issuance principle. Ireland also applies a stamp-duty-type tax, introduced in 1937 on the British model, with a rate of 1%. Existing work also identifies Finland, Poland, Cyprus and Malta among European countries with FTT-type instruments. These cases confirm that securities transaction taxes are not exceptional within Europe, although their design, scope and revenue performance vary substantially.⁴

Overall, the international landscape is heterogeneous. Some instruments, such as the UK stamp duty, the French FTT or the Spanish FTT, are close to an issuance-based equity transfer tax. Others are broader securities transaction taxes, stamp duties or financial transaction taxes applying to different instruments or market segments.

Table 1.1 provides an illustrative overview of selected existing taxes on equity and securities transactions, without attempting to provide an exhaustive or fully harmonised taxonomy.

The main lesson from existing national policies is clear. The success of an FTT depends less on the abstract principle of taxing financial transactions than on the details of its design. Taxes based only on the location of the intermediary or the trading venue are more vulnerable to avoidance. By contrast, taxes based on the issuance principle are more robust because the tax follows the security itself. The EU proposal examined here should therefore draw primarily on the UK, French, Italian and Spanish experiences, while avoiding the weaknesses of more easily circumvented systems.

⁴Several European countries previously levied similar taxes but later abolished them, notably the Netherlands in 1990, Germany and Sweden in 1991, Norway in 1993, Denmark in 1999 and Austria in 2000. These historical precedents should be interpreted with caution, as the abolished taxes often differed substantially in design from issuance-based equity transfer taxes such as the UK stamp duty or the French FTT.

Table 1.1: Selected existing taxes on equity and securities transactions

Jurisdiction	Main rate	Main scope and design features
France	0.4%	FTT on acquisitions of equity securities issued by French companies with market capitalisation above €1 billion. Primary issuance and several market operations are exempt; intraday transactions are outside the effective tax base.
Italy	0.2–0.4%	FTT on transfers of shares and equity-like instruments issued by Italian companies with market capitalisation above €0.5 billion. The lower rate applies to transactions executed on regulated markets or multilateral trading facilities. The Italian FTT also includes specific, albeit marginal, components for derivatives and high-frequency trading.
Spain	0.2%	FTT on onerous acquisitions of shares in Spanish companies with market capitalisation above €1 billion.
Belgium	0.12%-1.32%	Tax on stock-exchange transactions. The applicable rate and cap depend on the type of financial instrument. This design is less close to a pure issuance-based equity transfer tax.
Ireland	1%	Stamp duty on instruments or transfer orders transferring shares, stocks or marketable securities.
Greece	0.1%	Tax on sales of shares listed on a Greek regulated market or multilateral trading facility. The rate was reduced from 0.2% to 0.1% from 2024.
United Kingdom	0.5%	Stamp Duty / SDRT on purchases or transfers of shares in UK companies. Electronic transactions are generally collected through CREST. This remains the main benchmark for an issuance-based equity transfer tax.
Switzerland	0.15% / 0.30%	Securities transfer stamp tax on purchases and sales of Swiss or foreign securities when a Swiss securities dealer acts as contracting party or intermediary. The lower rate applies to Swiss securities and the higher rate to foreign securities.
Hong Kong	0.1%+0.1%	Stamp duty on the sale or purchase of Hong Kong stock. The duty is charged on every bought note and every sold note.
Singapore	0.2%	Share stamp duty on transfers of shares, computed on the purchase price or value of the shares transferred.
South Korea	0.15%-0.35%	Securities transaction tax on transfers of Korean shares. Rates differ across listed and unlisted markets and have changed repeatedly in recent years.
China	0.05%	Stamp duty on stock transactions, reduced from 0.1% to 0.05% from 28 August 2023.
Taiwan	0.3%	STT levied on sellers of securities. Reduced rates or suspensions apply to some instruments and transactions.
India	0.1%	STT applying to exchange-traded equity and derivatives transactions. Rates differ across delivery-based equity trades, intraday trades, futures and options.
South Africa	0.25%	Securities transfer tax on the transfer of listed and unlisted securities.

Notes: This table is illustrative rather than exhaustive. It focuses on existing taxes that are closest to an equity transaction or equity transfer tax. Rates and scope are simplified; exemptions, collection mechanisms and anti-avoidance rules differ substantially across jurisdictions.

3 The (former) European FTT project

The idea of a European financial transaction tax gained renewed political momentum after the 2007–2008 financial crisis. The crisis strengthened the view that the financial sector should make a fairer contribution to public finances and that new fiscal instruments could also help discourage socially unproductive short-term trading. The European Parliament called on the Commission to examine the issue in 2010, and the initiative was then strongly supported by France and Germany. In September 2011, the European Commission adopted a proposal for a Council directive establishing a common system of financial transaction tax across the European Union.

The Commission proposal was deliberately ambitious (Gabor, 2016). Its objective was not merely to create a new source of revenue, but also to harmonise existing national approaches, prevent fragmentation of the Single Market, ensure a fair contribution from the financial sector, and discourage transactions considered not to contribute to the economy. The proposal was based on a broad tax base and low rates. It would have applied to secondary-market transactions involving financial institutions, with minimum rates of 0.1% for shares and bonds and 0.01% for derivatives. The Commission described the approach as applying to all markets, all instruments and all actors. In particular, the proposed tax would have applied to gross transactions before netting and settlement, thereby including intraday transactions.

The expected revenue was substantial. For the EU as a whole, the Commission estimated that the proposal could raise around EUR 57 billion per year. Other estimates for the eleven Member States later involved in the enhanced cooperation procedure suggested annual revenues of around EUR 30–35 billion. These figures reflected the breadth of the initial proposal: a large share of expected revenue came not from the taxation of equity transactions alone, but from the inclusion of bonds and, especially, derivatives.

The project immediately encountered strong opposition. Because taxation requires unanimity in the Council, the proposal could not be adopted at EU-wide level. Several Member States were reluctant or hostile, especially those concerned about the impact on financial centres, market liquidity or the relocation of trading activity. The United Kingdom, Sweden and the Netherlands were among the most vocal opponents in the political debate. According to a contemporary review by the Fondation Robert Schuman, six countries eventually indicated formal opposition to the project in the context of the enhanced-cooperation decision: Bulgaria, Luxembourg, Malta, the United Kingdom, Sweden and the Czech Republic. Ireland and Latvia expressed reservations without formally opposing the principle.

As unanimity proved impossible, the debate shifted towards enhanced cooperation. In 2012, eleven Member States requested authorisation to proceed together: Belgium, Germany, Estonia, Greece, Spain, France, Italy, Austria, Portugal, Slovenia and Slovakia. The Council authorised enhanced cooperation in January 2013, and the Commission tabled a revised proposal in February 2013 for these participating countries. Estonia later withdrew from the process, leaving ten participating Member States. The use of enhanced cooperation was politically significant, as it would have been the first case of such a procedure in the field of taxation.

Despite this narrower framework, negotiations never reached a conclusion. The participating Member States continued to disagree on the scope of the tax, the treatment of derivatives, the residence and issuance principles, the allocation of revenues and the possible effects on non-participating Member States. The proposal remained blocked in the Council for years. In 2023, the Commission stated that the prospects of reaching an agreement were limited and that there was little expectation of an agreement in the short term. In its 2026 work programme, the Commission indicated its

intention to withdraw the proposal.

The proposal examined here is much less ambitious than the earlier European project. It does not seek to tax all financial instruments, all markets and all financial actors. It does not include bonds, derivatives or foreign-exchange transactions. It also does not attempt to tax all gross intraday transactions. Instead, it focuses on equity transfers, following the logic of existing national schemes such as the British stamp duty and the French FTT. The rate considered here, 0.5%, is higher than the 0.1% rate proposed by the Commission for shares and bonds, but the tax base is much narrower. The proposal is therefore best understood as a pragmatic equity transfer tax rather than as a comprehensive European FTT.

This narrower design has two advantages. First, it relies on mechanisms that have already been implemented in major financial markets. Second, it avoids reopening all the technical and political controversies that contributed to the failure of the earlier European project. The objective is not to revive the full 2011–2013 proposal, but to draw a practical lesson from it: an overly broad FTT may be politically fragile, whereas a simpler tax on equity transfers, based on the issuance principle and modelled on existing national systems, is more likely to be feasible.

4 Revenue potential at Member State level

The revenue estimates presented here follow an inference-based approach, rather than a purely hypothetical one (Capelle-Blancard and Persaud, 2025). The method is anchored in the observed revenue of the French FTT and then applied to equity trading volumes in other Member States. This is deliberately conservative: rather than assuming that the full statutory tax rate applies to all market transactions, it starts from what the French tax actually raises under the existing design, with its exemptions, its daily netting mechanism and the exclusion of intraday trading.

The reference year is 2024. In France, the FTT raised EUR 1,860 million, including EUR 528 million allocated to the Agence française de développement. According to ESMA⁵, the total value of equity transactions in France in 2024 was EUR 3,502,800 million. The implicit tax ratio is therefore:

$$\frac{1,860}{3,502,800} = 0.0531\%.$$

This figure is much lower than the statutory rate of the French FTT, which was 0.3% in 2024 (0.4% since April 2025). It implies that the effectively taxed base represents only:

$$\frac{0.0531\%}{0.3\%} = 17.7\%$$

of total equity trading volumes. In other words, the implicit exemption or out-of-scope rate is approximately 82.3%. This reflects the narrowness of the current French design: the tax applies to transfers of ownership recorded at the end of the day, not to all intraday transactions. Paradoxically, the most short-term transactions are therefore largely left outside the tax base.

The same implicit tax ratio is then applied to the equity trading volume of each Member State.⁶ The estimate at a 0.3% statutory rate is given by:

⁵ ESMA statistics on securities and markets, ESMA11-239717167-20877.

⁶ For some Member States, ESMA reports no equity trading volume in the dataset used for this exercise. These entries are therefore kept at zero for consistency, but they should not be interpreted as implying the complete absence of equity market activity.

$$R_i^{0.3} = T_i \times \frac{1,860}{3,502,800},$$

where T_i is the total equity trading volume in Member State i . The estimate at a 0.5% rate is obtained by assuming a proportional increase in revenue:

$$R_i^{0.5} = R_i^{0.3} \times \frac{0.5}{0.3}.$$

Table 1.2 reports the revenues estimated using this approach for each EU Member State.⁷ Overall, an EU-wide equity transfer tax at a 0.5% rate would raise approximately EUR 8 billion per year. This should be interpreted as an estimate for a narrow tax on equity transfers, not as an estimate for a broader FTT including bonds, derivatives or intraday transactions.⁸

The distribution of revenues would be highly concentrated. France alone would account for about 37% of total EU revenue, followed by the Netherlands with 23.5% and Germany with 19.1%. Together, these three countries would generate almost 80% of the total. Including Italy brings the share to around 86%. This concentration reflects the geography of equity trading within the EU rather than any specific assumption about tax capacity or political preferences.⁹

This concentration has two implications. First, the fiscal potential of the measure depends on a small number of large and liquid equity markets. Second, from an own-resources perspective, the tax would not mechanically generate revenue in proportion to Member States' GDP or population. This is not necessarily a weakness: the tax is designed to capture activity in financial markets, and market activity itself is highly concentrated. But it does mean that the allocation of revenues and the political presentation of the measure would need to be carefully designed.

⁷The Member State allocation is based on observed equity trading volumes reported in the ESMA dataset, rather than on the headquarters of the issuing firms. It should therefore be read as an operational approximation, not as a precise legal allocation under the issuance principle. Existing national FTTs are not deducted from these gross estimates.

⁸These illustrative figures differ from previous estimates of FTT revenues (Capelle-Blancard and Persaud, 2025) for methodological reasons. In earlier work, transaction volumes were based on a combination of World Bank and Refinitiv data for 2022, and revenues were estimated by assuming that 15% of total turnover would remain taxable after exemptions and that trading volumes would fall by 20% after the introduction of the tax. At a 0.5% statutory rate, this amounts to applying an effective revenue ratio of approximately 0.06% to total trading volumes. The estimates reported here use ESMA (and WFE) trading volumes instead, and apply the implicit French revenue ratio observed in 2024, scaled from the French statutory rate to a 0.5% rate. The difference between the two sets of results therefore reflects both the use of a different data source for trading volumes and a different effective tax ratio. These figures should be read as illustrative orders of magnitude rather than as directly comparable estimates.

⁹As an illustrative benchmark, applying the same implicit revenue ratio to WFE equity trading volumes gives much larger orders of magnitude for major non-EU markets: approximately EUR 116 billion for the United States, EUR 6.9 billion for Japan, EUR 28.6 billion for China, and EUR 178 billion at the world level. These figures should be interpreted with great caution. WFE trading volumes are not directly comparable with the ESMA data used for the EU Member State estimates. They are therefore provided only as indicative orders of magnitude, not as directly comparable revenue estimates.

Table 1.2: Estimated revenues by EU Member State

Member State	Code	Equity trading volume EUR million	Estimated revenue EUR million, 0.5% rate
Austria	AT	29,800	26.4
Belgium	BE	69,000	61.1
Bulgaria	BG	200	0.2
Cyprus	CY	900	0.8
Czechia	CZ	4,300	3.8
Germany	DE	1,802,500	1,595.2
Denmark	DK	128,600	113.8

European Union	EU27	9,417,600	8,334.6

5 Responses to common objections

The debate on FTTs is marked by a recurring set of objections. Many of them are serious and should not be dismissed. However, they often refer to very broad FTT schemes, whereas the proposal considered here is narrower: a tax on equity ownership transfers, based on the issuance principle, at a moderate rate. This distinction is crucial. The question is not whether any possible FTT would be desirable, but whether this specific design can provide a robust and workable own resource.

1. The FTT would reduce market liquidity.

This objection is partly correct but often overstated. A FTT increases the cost of trading and is therefore expected to reduce trading volumes (International Monetary Fund, 2010; Colliard and Hoffmann, 2017). This is not necessarily a problem. A fall in very short-term trading is one of the intended effects of such a tax, especially when a large share of market activity consists of rapid, low-margin transactions whose private profitability may exceed their social value. Some high-frequency strategies may improve liquidity and price discovery, but others mainly reflect a technological arms race for speed, latency arbitrage, order anticipation or very short-lived quote revisions. These activities can impose costs on other market participants, increase the resources devoted to trading infrastructure, and generate little additional information for long-term capital allocation.¹⁰

The relevant question is not whether turnover declines, but whether useful liquidity is harmed. Existing evidence on modern, low-rate equity FTTs suggests that turnover may fall, but without clear evidence of significant deterioration in liquidity or volatility (Colliard and Hoffmann, 2017).

The Swedish case is often used as an argument against FTTs, but its main problem was poor design: the tax was linked to domestic intermediaries and was therefore easy to avoid by relocating transactions. It is not evidence that a well-designed issuance-based tax necessarily decreases liquidity. The proposal considered here focuses on ownership transfers and can preserve exemptions for genuine market-making activities.

2. The FTT would increase volatility.

The theoretical effect of an FTT on volatility is ambiguous. If all market participants are perfectly rational and liquidity is always beneficial, then a tax may appear harmful. But if markets also include noise trading, herding, excessive short-termism or self-reinforcing speculation, then reducing some transactions may improve rather than worsen price formation (Matheson, 2011; McCulloch and Pacillo, 2011).

Empirically, the claim that FTTs mechanically increase volatility is not supported by the experience of existing low-rate equity taxes.

3. The FTT would raise the cost of capital for firms.

This objection relies on a plausible but indirect mechanism: a transaction tax could reduce trading volumes; lower trading volumes could reduce market liquidity; lower liquidity could

¹⁰The literature on individual investors shows that more frequent trading often reduces net performance (De Bondt and Thaler, 1995; Shleifer, 2000; Odean, 1999; Barber and Odean, 2000, 2001), while recent work on high-frequency trading emphasises the private gains but limited social value of ever-faster execution (Budish et al., 2015; Aquilina et al., 2022).

increase the return required by investors; and this, in turn, could raise firms' cost of capital. The first link in this chain is credible: an FTT is expected to reduce trading volumes. The key question, however, is whether this reduction in turnover translates into a meaningful deterioration in liquidity and then into a higher cost of capital.

The theoretical link between liquidity and expected returns is well established (Amihud and Mendelson, 1986; Amihud, 2002). But the empirical relevance of this channel for a low-rate equity transfer tax is much less clear. Evidence on the French FTT shows that trading volumes declined, but the effects on market quality were limited and did not provide evidence of a large disruption to liquidity. If the liquidity channel is weak or breaks at this stage, there is little reason to expect a material effect on firms' cost of capital.

Direct evidence is also reassuring. Fraichot (2017) studies the effect of an FTT on corporate cost of capital and finds an insignificant impact in highly liquid equity option markets. More recently, Do (2025) studies the 2012 French FTT and finds a positive effect on corporate investment, especially where the tax induced a shift from short-term to longer-term ownership. This suggests that any increase in transaction costs may be offset by a reduction in short-termism, rather than mechanically raising firms' financing costs (Fraichot, 2017; Do, 2025).

4. The FTT would harm investment and competitiveness.

This objection assumes that the presence of a FTT makes a financial centre unattractive. Existing experience suggests otherwise. The United Kingdom has maintained a stamp duty on share transactions for centuries while remaining one of the world's leading financial centres. France, Italy and Spain have also introduced modern equity FTTs without undermining the functioning of their equity markets.

Competitiveness concerns should therefore be assessed in relation to the design of the tax. A badly designed tax can create distortions. A tax based on the issuance principle, applied at a moderate rate and limited to equity transfers, is much less likely to damage competitiveness than a tax based only on the location of intermediaries or trading venues.

5. The FTT would lead to relocation.

Relocation is a serious risk when the tax is based on the location of the broker, the exchange or the intermediary. This was the central weakness of the Swedish experiment in the 1980s. It is not the logic of the proposal considered here.

Under the issuance principle, the tax follows the security, not the marketplace. A share issued by a company in a participating Member State remains within the scope of the tax even if it is traded through a foreign intermediary or on an alternative platform. This substantially limits the scope for relocation, because moving the transaction does not remove the underlying security from the tax base.

6. The FTT would be easy to avoid.

Avoidance is possible for any tax, but the risk is much lower when the tax is attached to the transfer of legal ownership. The British stamp duty illustrates this logic: the tax is connected to the recognition and settlement of ownership. The French system also shows that an equity transfer tax can be implemented in a modern, highly internationalised market.

The main remaining issue is substitution towards untaxed instruments or arrangements, including derivatives. This is a valid concern. However, the proposal examined here is deliberately conservative and focuses on the most robust part of the tax base: equity ownership

transfers. Additional anti-avoidance rules could be considered if substitution became significant, but the existence of possible avoidance margins is not a reason to abandon the tax altogether.

7. The FTT would hit ordinary savers.

This objection is often politically powerful but economically incomplete. The direct payer may be the buyer of the share, but the economic incidence of the tax depends on trading behaviour, portfolio structure and market intermediation. Ordinary savers typically trade much less frequently than professional intermediaries or short-term investors. For buy-and-hold investors, the effective annual cost of a small transaction tax is not significant.

The French case suggests that a substantial share of the tax would also be collected from foreign investors. In 2024, non-residents held 50% of the capital of French-resident CAC 40 companies. Under the (plausible) assumption that trading shares are broadly proportional to ownership shares, roughly half of the revenue from an issuance-based tax on French shares would therefore be collected from non-resident investors. For an EU-wide tax, the share paid by non-EU investors would require a dedicated calculation, since intra-EU cross-border holdings would no longer count as external to the Union. The French evidence nevertheless shows that such taxes are not borne only by domestic households.

The redistributive profile of the tax is also important. Equity ownership is highly concentrated among wealthy households. In the euro area, the wealthiest 10% of households own about 82% of directly held listed equities; in France, the concentration is even higher, at close to 88%.¹¹ By contrast, direct share ownership is limited among the rest of the population. Even when the FTT is ultimately borne by households, it therefore falls disproportionately on wealthier investors and more frequent traders, rather than on ordinary savers. This makes the FTT more progressive than broad-based taxes on labour income or consumption.

8. The FTT would penalise market-making and useful liquidity provision.

This is a design issue rather than a decisive objection. The purpose of the tax is not to penalise genuine liquidity provision, but to tax equity ownership transfers while preserving the market functions that are necessary for orderly trading. Existing FTTs already address this issue through clear exemptions. The French FTT, for example, exempts market-making activities carried out by investment firms or credit institutions, including when these activities are conducted abroad. It also exempts market-making activities carried out on behalf of the issuer in order to support the liquidity of its securities. These exemptions are explicitly designed to protect useful liquidity provision.

The key challenge is therefore to calibrate exemptions carefully. If they are too narrow, useful liquidity provision may be affected. If they are too broad, the tax base is unnecessarily eroded.

9. The FTT would be administratively complex to collect.

The practical experience of existing taxes suggests the opposite. Equity transfer taxes can be collected through settlement, reporting or central securities infrastructure. The UK stamp duty and the French FTT show that such taxes are technically feasible.

That said, the quality of the collection mechanism matters. The French experience also shows that transparency, access to data and administrative control are important. A European own

¹¹<https://www.afg.asso.fr/app/uploads/2025/02/Etude-AFG-OEE-2025.pdf>

resource should therefore be designed with clear reporting obligations and strong cooperation between tax authorities, market supervisors and settlement infrastructures.

6 Review of existing surveys on public opinion

Public opinion is one of the relative strengths of the FTT proposal. The available evidence should nevertheless be interpreted with caution. The most detailed EU-wide survey is now somewhat dated, while the most recent survey evidence covers only a limited number of Member States. Taken together, however, the results point to a consistent pattern: financial transaction taxes tend to attract broad public support, especially when they are presented as a way to make the financial sector contribute to public goods, development, climate action or the costs of crises.

The main EU-wide reference remains the 2011 Eurobarometer survey commissioned by the European Parliament in the aftermath of the financial crisis.¹² In that survey, 61% of Europeans supported the principle of a tax on financial transactions, while 26% were opposed and 13% expressed no opinion. Support was higher in euro area countries, at 63%, than in non-euro area countries, at 54%. The wording of the question explicitly stated that the tax would be very low and would apply to transactions between financial operators, not to the general public.

The same survey also provides useful information on the reasons behind public support. Among respondents in favour of the principle of the tax, the main motivation was to combat excessive speculation and help prevent future crises, followed by the idea that financial actors should contribute to the costs of the crisis. Reducing public deficits and financing innovative policies, including climate, environment and development aid, were also mentioned, but less frequently. This suggests that the public appeal of the FTT is linked not only to revenue-raising, but also to a broader perception of fairness in the taxation of the financial sector.

The objections expressed by opponents in the 2011 survey were also informative. Among those opposed to introducing the tax at EU level as a first step, the main concern was feasibility: some respondents believed that such a tax could only be introduced globally. Other concerns related to competitiveness, the risk that only European financial actors would contribute, and possible capital outflows from the EU. These objections closely mirror the arguments raised in the policy debate. They also reinforce the importance of explaining why the proposal considered here is narrower, issuance-based, and modelled on existing national systems.

More recent evidence is provided by a 2024 survey conducted by Focus 2030 and Stack Data Strategy in France, Germany and Italy, ahead of the European Parliament elections.¹³ The survey was carried out between 16 and 22 February 2024, with representative samples of around 1,500 respondents in each of the three countries. It found that 57% of respondents supported a European financial transaction tax, while 80% were either in favour or would not oppose such a tax if it were used to finance the fight against global poverty and climate change. Only 13% opposed the measure. Support, or non-opposition, was highest in France, at 82%, with only 9% opposed.

Available surveys suggest that the FTT is more popular than many other tax instruments, especially when framed as a modest levy on financial transactions rather than a tax on ordinary households. From a political communication perspective, the strongest framing is therefore not technical harmonisation, but fairness: a small contribution from financial-market activity to finance

common European and global priorities.

7 Possible extensions

The proposal examined here is intentionally limited to equity ownership transfers. This narrow scope is useful for adoption, but it could later serve as a platform for two main extensions: first, the inclusion of intraday equity transactions; second, the extension of the tax base to other financial instruments, such as derivatives or crypto-assets.¹⁴

7.1 Extension to intraday equity transactions

The most natural extension would be to include intraday equity transactions. Under the French model, the tax applies to net acquisitions recorded at the end of the trading day. Transactions opened and closed within the same day are therefore outside the effective tax base, including many high-frequency and very short-term strategies. This is a major limitation: the tax applies to investors who hold shares at least until the end of the day, while many of the shortest-term transactions remain untaxed.

Including intraday transactions would broaden the base, increase revenues and improve the coherence of the tax. In the French case, the effectively taxed base represents only a small share of total equity trading volumes, precisely because the tax is collected on transfers of ownership rather than on all transactions. From an economic point of view, it is difficult to justify taxing longer-term investors while leaving the fastest and most speculative transactions outside the scope of the tax.

The main obstacle is operational rather than conceptual (Capelle-Blancard, 2024b). A tax on end-of-day ownership transfers can be collected through central securities depositories such as Euroclear. A tax on intraday transactions, by contrast, requires reliable information at the level of order execution and trading venues. This would imply a change in the collection architecture. One possible route would be to rely more directly on transaction-level reporting under MiFID II, which already provides regulators with detailed information on market transactions.

This extension should not be confused with the taxation of genuine liquidity provision. Market-making is an economic function, not a trading horizon. Some intraday transactions contribute to liquidity, but many others do not. Existing FTTs already include targeted exemptions for market-making activities, including in France. A blanket exclusion of all intraday trading is therefore not the right way to protect liquidity. It amounts to adding a broad and poorly targeted exemption on top of already existing protections. A well-designed EU FTT should preserve clear market-making exemptions, but should not exclude all intraday trading by default.

7.2 Extension to other financial instruments

A second extension would consist in broadening the tax base beyond equity transfers. The earlier European Commission proposal covered not only shares, but also bonds and derivatives. Such a broader base would raise larger revenues and reduce substitution towards untaxed instruments. It would also address a legitimate concern: if only equity transfers are taxed, investors may replicate

¹⁴Another possible extension would be a green FTT, either through the allocation of revenues to climate and environmental objectives or through differentiated rates linked to issuers' environmental performance; see (Capelle-Blancard, 2027).

some exposures through derivatives or other instruments that are economically close to the taxed transaction.

This extension is, however, more complex than the inclusion of intraday equity transactions. Derivatives raise difficult questions of valuation, netting, maturity, notional amounts and economic equivalence. A simple tax on the notional value of derivatives would not be appropriate for all contracts, while a tax on premia or market values may be harder to harmonise and enforce. Crypto-assets raise additional issues, including the identification of taxable events, the location of platforms and intermediaries, and the treatment of decentralised transactions.

For these reasons, the core proposal should remain focused on equity transfers. Once the legal and administrative framework is established, the EU could consider targeted extensions to instruments that are close substitutes for equity transactions, especially equity derivatives. Broader extensions to bonds, foreign exchange or crypto-assets should be treated as separate policy choices, requiring specific design and impact assessment. The priority is therefore sequential: first establish a robust equity transfer tax; then broaden the base where substitution risks, feasibility and revenue potential justify doing so.

A One-Off Wealth Tax to Fund a Sovereign EU Fund

Adrien Fabre

Who owns and steers Europe’s productive capital, from critical infrastructure to frontier technologies, is a first-order public question. Through sovereign wealth funds (SWFs), citizens of some 40 jurisdictions hold a collective stake in large firms and long-term investments. Such funds are no longer the preserve of resource-rich states: China, Singapore, Australia and South Korea each run one worth more than 10% of their GDP, and Canada launched a national fund in 2026 financed by public debt. Worldwide, SWFs manage assets worth close to 13% of global GDP, yet the European Union has no comparable fund.

This appendix argues that the EU should build one and finance it with an exceptional, one-off tax on large individual wealth. The revenue could serve as a new own resource paid into the EU budget, or repay the common NextGenerationEU debt contracted during the Covid crisis, but we propose a more strategic use. Sized at 5% of EU GDP, the levy would build up a fund whose assets would eventually reach about twice that common debt, so that its long-run dividends would exceed the interest owed several times over. Rather than shrink the Union’s balance sheet by repaying the debt, we would invest the proceeds, at a time when major investments are needed for the ecological transition and for competitiveness. The underlying levy is, in any case, fair, popular and non-distortive.

The proposal deliberately avoids the pitfalls that have historically undermined recurrent wealth taxes. It is a *one-off* levy, assessed on the net wealth each resident holds on a single reference date (1 January 2027), and paid over thirty years at low annual marginal rates: 0.1% on wealth between EUR 1 and 10 million, 0.3% between EUR 10 and 100 million, and 0.5% above EUR 100 million. Because the base is fixed in the past, the levy is a lump sum in the economic sense: no decision taken after 2027, whether to invest, to found a company or to emigrate, can change what is owed, so the tax does not distort future accumulation and activity. The low annual rates keep the tax non-confiscatory and comfortably within constitutional bounds. Liquidity is addressed head-on: payment is reduced if a taxpayer’s wealth drops and the taxpayer may pay in company shares. Finally, a Deferral Account guarantees that the levy is enforced if the taxpayer emigrates or dies.

The proposal adapts the deferral and one-off mechanism designed for the Californian wealth-tax bill ([California State Legislature, 2023](#)). It adopts the low-rate one-off logic of [Pisani-Ferry and Mahfouz \(2023\)](#), who recommended an exceptional levy of 5% of GDP spread over thirty years to finance the climate transition.

The instrument also rests on solid economic foundations. [Farhi \(2010\)](#) shows that a one-off capital levy is the efficient response to a negative fiscal shock, precisely the case created by the pandemic-era debt, the security build-up and the financing of the transition. Progressive wealth taxation is independently justified on distributive grounds: [Saez and Zucman \(2019\)](#) argue that it is the most appropriate tool for restoring progressivity at the very top, since the ultra-wealthy report little taxable income.

The remainder covers the proposal (Section 1), revenue estimates (2), interaction with existing taxes (3), objections (4) and variants (5).

1 Proposal

1.1 A one-off tax, payable over thirty years

We propose a one-off tax on individual net wealth, assessed on the wealth each resident holds on 1 January 2027. The tax is strictly individual: wealth is attributed to natural persons, with couples assessed on their respective shares, so as to avoid the marriage penalties and avoidance opportunities associated with household-level assessment.

The headline schedule is a one-off liability levied at the following marginal rates: 3% on the fraction of individual wealth between EUR 1 and 10 million, 9% on the fraction between EUR 10 and 100 million, and 15% on wealth above EUR 100 million. This liability is not due immediately. It is spread over thirty years, so that in any given year the taxpayer owes one thirtieth of the total: the annual tax schedule is 0.1% on wealth between EUR 1 and 10 million, 0.3% between EUR 10 and 100 million, and 0.5% above EUR 100 million. These annual rates are deliberately calibrated well below the return on capital, so that the tax can in principle be paid out of the income the wealth generates, leaving the principal intact.

The one-off character is the central design choice. A permanent wealth tax changes the incentive to accumulate, to invest and to remain resident on an ongoing basis; the empirical literature finds that such taxes can generate behavioural responses, from portfolio reshuffling to migration (Brühlhart et al., 2022; Durán-Cabré et al., 2019). A one-off tax assessed on a past reference date is, by construction, a lump-sum tax: it does not distort decisions taken after the reference date, because no future choice can change the liability. This is the classical efficiency argument for capital levies, and it is the reason Pisani-Ferry and Mahfouz (2023) and the Californian bill favoured an exceptional rather than a recurrent instrument.

1.2 Payment, deferral and the annual minimum

Each year, the taxpayer must pay the *smaller* of two amounts: (i) one thirtieth of their initial liability, indexed to inflation and increased by a deferral charge; or (ii) the annual schedule (0.1% / 0.3% / 0.5%) applied to their *current* wealth. The second option protects taxpayers whose wealth has fallen: someone who has become poorer since 2027 pays less, in line with their ability to pay. The tax ceases to be owed after thirty years of payment, or earlier if the taxpayer settles their remaining liability in full.

The deferral charge reflects the fact that postponing payment is equivalent for the taxpayer to paying upfront, hence it reflects the return the taxpayer earns on the deferred sum. We set it at 3% per year for the tax due below EUR 10 million, 5% between EUR 10 million and 100 million, and 7% above EUR 100 million. These figures are aligned with the empirically documented gradient of returns to wealth: larger portfolios earn systematically higher average returns (Chancel et al., 2022). Aligning the charge with the return on capital ensures that deferral is neither confiscatory nor a subsidy to the wealthy, and removes the incentive to game the timing of payments.

1.3 Payment in kind

Liquidity constraint is the objection most often raised against wealth taxes: a taxpayer may be rich on paper yet hold most of their wealth in illiquid form, such as a stake in an unlisted company, real estate or an art collection, that generates little cash, so that a tax payable in cash could force them to sell assets, sometimes at a discount.

The proposal neutralises it through a graduated set of payment options. First, the administration accepts payment in non-cash liquid assets, in particular shares in listed companies, valued at market price on the day of transfer. A taxpayer whose wealth consists mainly of a quoted equity stake can therefore discharge the tax without selling on the market and without any cash outlay. Second, on a case-by-case basis, the administration may accept payment in illiquid assets, such as shares in non-listed companies, to the extent that the taxpayer's liability exceeds their liquid assets. This mirrors the logic of the Californian bill, which allowed liquidity-constrained taxpayers holding designated highly illiquid assets (typically start-up equity) to attach a claim to those assets rather than face an immediate cash assessment ([California State Legislature, 2023](#)).

Payment in shares has an important corollary for the objection that a wealth tax penalises young, capital-intensive firms relative to established ones. Because the founder of a start-up can hand over a fraction of their shares rather than cash, the tax does not force the sale of the company and it does not require the firm to distribute dividends it cannot afford. In case where the tax could make the taxpayer lose control over their company (by reducing their stake below 50%), the administration may accept payment in non-voting shares.

1.4 Deferral Accounts

Unless they settle their entire liability in the first year, taxpayers must open a Deferral Account (DA): a contract with the State to which they attach assets of sufficient value to cover the tax liability. The DA has two functions. It secures the State's claim: the outstanding liability is recovered when the taxpayer dies or moves their tax residence outside the EU, whichever comes first, and the account is closed only once the tax has been paid in full. It supports the payment-in-kind mechanism, since attached assets can be realised to discharge the debt.

A missing payment triggers a penalty equal to inflation plus 10% per year on the overdue amount. This penalty accrues within the DA and is ultimately recovered when the attached assets are sold or generate dividends, so that non-payment is costly but never forces an immediate ownership transfer. The combination of low annual rates, deferral, payment in kind and asset-backed recovery is what makes the tax simultaneously enforceable, non-distortive and respectful of taxpayers' liquidity constraints and asset control.

1.5 Governance and mandate of the fund

The proceeds endow a European sovereign wealth fund under democratic control. Its board would be appointed by the political groups of the European Parliament, each group naming board members and exercising a voting right proportional to its number of seats in the Parliament, so that the fund's direction reflects the Union's democratic balance rather than the discretion of a single executive.

The fund's mandate would be threefold: to hold a broadly diversified portfolio of equities, so as to spread risk and secure a stable return; to steer the ecological transition; and to select strategic investments that strengthen Europe's future-preparedness. On the model of the recent Canadian national fund, the mandate would give priority to *primary* investments (initial public offerings,

capital increases and other subscriptions of newly issued equity) in European companies with a strategic dimension or a sustainable project, so that the fund channels fresh capital into productive investment rather than mostly reallocating ownership of existing shares.

2 Revenue estimates

2.1 Method and assumptions

Revenue is estimated by microsimulation on the 2023 wealth distributions of the World Inequality Database (WID).¹ Two successive haircuts are applied to the base throughout: 15% for asset-price depreciation and a further 15% for evasion and valuation discounts.

Table 2.1’s revenue figures are those of the proposed tax’s three marginal bands. Column *a* is the 0.1% levied on the slice of wealth between EUR 1 and 10 million; column *b* the 0.3% on the slice between EUR 10 and 100 million; and column *c* the 0.5% on all wealth above EUR 100 million. The central scenario is the sum of these three bands, $a + b + c$ (also shown as a share of 2023 GDP). Column *d* reports a separate band that does not belong to the central schedule: a 2% rate on wealth above EUR 1 billion, used only to illustrate a top-heavy variant that would use 2% as the marginal rate on billionaire wealth, so that the top-heavy figure is $c + \frac{3}{4}d$. All figures are in EUR million per year.

2.2 Results

The central scenario, which combines the three low brackets, raises about EUR 26 billion per year for the EU, or close to EUR 790 billion over the thirty-year horizon. This represents 4.5% of EU GDP, in the range of the 5%-of-GDP benchmark independently proposed by [Pisani-Ferry and Mahfouz \(2023\)](#) to finance the French energy transition, and about twice the EU’s common (NextGenerationEU) debt. The revenue broadly tracks the distribution of large fortunes across the Union: Germany, France, Italy and Spain together account for 75% of total revenue. This geographic profile is a feature rather than a drawback. The proceeds are not consumed but channelled into a European fund that reinvests in productive companies; a fund managed on a competitiveness logic would in any case direct much of its capital towards the Member States that host Europe’s largest firms, so that the country pattern of contributions and the country pattern of investment would broadly coincide.

These estimates are deliberately conservative for two reasons. They cut the base by two successive 15% haircuts, both generous. The 15% allowance for evasion and valuation discounts sits well above the leakage a well-enforced one-off levy should suffer: [Seim \(2017\)](#) finds that the taxable base contracts by at most 1% in the short run, and [Advani and Tarrant \(2021\)](#) put the medium-run figure at less than 10% for a 0.5% wealth tax. The 15% allowance for depreciation is also cautious,

¹For most Member States, we use the tabulation that underlies the [WID Wealth Tax Simulator](#), which reports, for a grid of euro thresholds, the total net wealth and the number of adults above each threshold. This dataset is the more adequate source, for two reasons: its grid already includes the statutory cut-offs (EUR 1, 10, 100 million and 1 billion), so each bracket’s base can be read off directly; and it smooths the top tail, so it resolves the extreme fortunes on which the upper brackets depend. The eleven smaller Member States that the simulator omits are completed from the raw WID distributional-national-accounts data, which report the average wealth within each of 127 population brackets, up to the top 0.001%. Applying the schedule to those bracket averages reproduces the lower brackets well but resolves the very top less finely. Because these states are small (their combined contribution is about EUR 0.6 billion), this has no material effect on the EU total.

and compounded by our use of 2023 wealth data. Indeed, the tax would be assessed on wealth held on 1 January 2027: since asset prices have risen since 2023, the true 2027 base, and hence the revenue, would be larger.

Table 2.1: Estimated revenue of a one-off wealth tax in the first year, by EU Member State (EUR million per year) The GDP column reports annual central revenue as a share of GDP.

3 Interaction with existing taxes

The proposed levy would be *additional* to, not a substitute for, the taxes Member States already apply to wealth. Within the EU only Spain still operates a comprehensive recurrent net-wealth tax, and the few other national instruments are narrow. Crucially, all of them share a feature that the present proposal deliberately avoids: they largely spare the business assets that make up the bulk of very large fortunes, so the overlap with our levy is small.

Spain is the leading case. Its recurrent wealth tax is regionally administered, and several regions (notably Madrid and Andalusia) had granted 100% relief until the central government introduced, in 2022, a Solidarity Tax on Large Fortunes (ITSGF) to reclaim that base, with marginal rates of 1.7% above EUR 3 million up to 3.5% above 11 million. Yet the Spanish tax exempts business assets: shares held by owner-managers who hold a qualifying stake, play a managerial role and draw most of their income from the firm are relieved, and the primary residence is partly exempt. On top of this, a cap limits the combined income-and-wealth-tax bill to 60% of taxable income; but the resulting relief may not exceed 80% of the wealth-tax liability, so that at least 20% of it is always due (Article 31 of Law 19/1991). In practice this floor caps the effective wealth-tax rate of the asset-rich but income-poor at one fifth of the statutory rate, about 0.7% rather than the headline 3.5%. Together these carve-outs and caps let the very wealthiest largely escape the tax, and avoidance responses to it are well documented ([Directorate-General for Taxation and Customs Union \(European Commission\), 2026](#)).

France abolished its general wealth tax (ISF) in 2018 and replaced it with a narrow tax on real-estate wealth (IFI), at 0.5%–1.5% on net property above EUR 1.3 million, leaving financial and business wealth untaxed.

The Netherlands has no more net-wealth tax: its “Box 3” regime taxed a notional return on savings and investments within the income tax, an approach the Supreme Court struck down in 2021 and again in 2024 (Section 4). From 2028 it is to be replaced by the Box 3 Actual Return Act, which taxes the *real* return on wealth: an annual mark-to-market (accrual) tax on the change in value of most assets and debts, combined with a realisation-based capital-gains tax on real estate and on shares in start-ups. This remains a tax on the return to wealth, not on the wealth stock itself, and so leaves the base our levy targets untouched.

Belgium levies a 0.15% annual tax on securities accounts worth at least EUR 1 million, a narrow charge that reaches listed portfolios but not directly held business stakes.

The proposed levy is therefore complementary rather than duplicative. Because it is one-off, values assets at market and grants *no* business-asset exemption, it falls, for very-high-net-worth individuals, precisely on the unlisted-company and financial holdings that the national taxes spare, while adding only 0.1% per year at the bottom of the schedule (above EUR 1 million). Where a taxpayer is simultaneously liable to a national recurrent wealth tax (the Spanish solidarity tax or the French IFI), the proposal treats them as cumulative, since even in the most heavily taxed cases the combined annual burden stays below the return on capital and therefore within the bounds courts have treated as non-confiscatory (Section 4).

4 Responses to main objections

4.1 Expatriation

The objection most often raised against wealth taxes is that the wealthy will simply leave. This concern is real for a recurrent tax, but it has little force against a one-off levy assessed on residence at a fixed past date. Because the liability is fixed by where a taxpayer lived on 1 January 2027, no later move can change what is owed. Emigration therefore cannot erase the tax, only the ease of collecting it, and that is what the Deferral Account is designed to secure. The outstanding balance is attached to assets and crystallises when the taxpayer dies or transfers their tax residence outside the EU, so that leaving triggers, rather than avoids, payment. This is the same logic as an exit tax, applied to a liability that was already fixed before any departure.

4.2 Liquidity

Another common objection is that wealthy taxpayers, though rich on paper, may lack the cash to pay. The design answers this on two levels: the annual rate is low (at most 0.5% of wealth, payable out of normal capital income rather than principal), and payment can be made in listed shares or, in genuinely illiquid cases, in kind, so that no market sale or cash outlay is required.

4.3 Reduced investment and production

A wealth tax could in principle reduce private investment by lowering the after-tax return to capital and by consuming tax revenue through public spending, eventually lowering GDP. This concern does not apply here for two reasons. First, the tax is one-off and backward-looking, so it does not alter the marginal return on any investment decided after 2027. Second, and decisively, the revenue is earmarked to a European sovereign wealth fund: assets withdrawn from private portfolios are re-invested, not consumed, so the aggregate capital stock is preserved and the composition merely shifts from private to collective ownership. The fund's returns are designed to more than cover the servicing of the common debt, turning a one-off levy into a permanent public asset.

4.4 Deterring entrepreneurs

The claim that wealth taxes deter entrepreneurship applies to *recurrent* taxes that repeatedly claw back the fruits of success. It does not apply to a one-off tax on a past stock. An entrepreneur contemplating a new venture in 2028 faces no wealth-tax consequence from success, because the reference date has passed. The incentive to create, take risks and build is therefore left intact, which is precisely why [Pisani-Ferry and Mahfouz \(2023\)](#) and the classical public-finance literature on capital levies favour exceptional over permanent instruments.

4.5 Valuation

A recurring objection is that wealth is hard to value, especially unlisted businesses, real estate and art. The one-off design blunts this objection at the root: because the tax is assessed on a single reference date, assets need to be valued only once, exactly as they already are at death for inheritance tax, rather than re-valued every year. The recurring administrative cost that weighs on permanent wealth taxes therefore does not arise.

The experience of countries that value wealth annually shows the task is feasible but must be done at market value. Norway, which has levied a net-wealth tax without interruption since 1892, values listed shares at market, primary dwellings by hedonic pricing and other real estate by construction cost, and unlisted firms at their book value excluding intangible assets ([Directorate-General for Taxation and Customs Union \(European Commission\), 2026](#)). That last convention systematically under-values young, intangible-intensive companies, the very firms whose value lies in their brand, technology or growth prospects, so Norway's base is, if anything, too generous to business owners ([Grindaker and Vestad, 2025](#)). We therefore assess all assets at fair market value.

4.6 The low yield of past wealth taxes

Sceptics point out that recurrent wealth taxes have historically raised little, around 0.2% of GDP in France (ISF) and Spain, and roughly 0.1% in the former German and Austrian taxes ([Directorate-](#)

General for Taxation and Customs Union (European Commission), 2026). This is a critique of how those taxes were designed, not of wealth taxation as such. Their yield was hollowed out by three features that the present proposal rejects. First, generous exemptions for business assets. Second, income-based caps: for instance, France’s cap let the billionaires be taxed at an effective rate of less than 0.1% (Directorate-General for Taxation and Customs Union (European Commission), 2026). Third, annual assessment on a mobile base, which invited migration and avoidance year after year. Our levy grants no business-asset exemption, has no income cap (it is instead capped by an ability-to-pay ceiling on *current wealth*), and is assessed once on a past stock that cannot emigrate. It is precisely because it corrects these three defects that it raises as much revenue as old taxes did despite significantly lower tax rates.

4.7 Constitutionality

Wealth taxation is not unconstitutional as such in any EU jurisdiction. The concern that can make a wealth tax fall foul of a constitution is that it becomes confiscatory, taking so large a share of asset returns that it amounts to an expropriation rather than a tax. Low rates dispose of that concern: an annual charge of at most 0.5% of wealth, only a fraction of the normal return on capital, leaves the principal intact and stays far from any confiscation threshold. The history of national wealth taxes, reviewed below, confirms that they were struck down or abandoned for specific, avoidable defects, unequal valuation, taxation of a fictitious return, or genuinely confiscatory rates, and never because taxing wealth is inherently impermissible.

Germany. The Federal Constitutional Court suspended the wealth tax in its 1995 decision (2 BvL 37/91) not because wealth taxation is inherently unconstitutional, but because real estate was valued far below market while financial assets were valued at market, violating the equality principle of the Basic Law (Bundesverfassungsgericht, 1995). The same decision advanced the *Halbteilungsgrundsatz*: that wealth and income tax combined should not take away more than roughly half of the potential return of the taxed assets. Two points defuse this. First, the Court itself, in a later ruling, held the *Halbteilungsgrundsatz* not to be legally binding (Directorate-General for Taxation and Customs Union (European Commission), 2026). Second, the proposed tax would satisfy it in any case: an annual charge of at most 0.5% of wealth is only a small fraction, of the order of a tenth, of the normal return on capital, so that even added to income tax the combined burden stays far below half of that return. A uniformly market-valued, low-rate one-off tax thus avoids both defects that felled the German tax.

Spain. The Constitutional Court *upheld* the central solidarity wealth tax in December 2023 against challenges from several regions, confirming that a wealth tax is compatible with the Spanish constitution (Tribunal Constitucional de España, 2023).

The Netherlands. The Netherlands abolished its genuine net-wealth tax in 2001 for practical, not legal, reasons: the old tax was widely avoided or evaded and raised little. The wealth tax was folded into the income tax as “Box 3”, which taxes a *notional* (assumed) return rather than actual wealth or actual income, a design chosen for administrative simplicity, not because taxing wealth was thought unconstitutional. It is precisely the taxation of a *fictitious* return that the Supreme Court struck down, in the 2021 “Christmas Judgment” and again in 2024, as an infringement of the right to property and the prohibition of discrimination under the European Convention on Human

Rights (Hoge Raad der Nederlanden, 2021). The Netherlands is now moving to a tax on *actual* returns from 2028. A charge levied on *actual* wealth, with an ability-to-pay safeguard, does not share this flaw; if anything the Dutch saga shows that taxing real wealth is on firmer legal ground than taxing an imputed one.

France. The Conseil constitutionnel has repeatedly upheld wealth taxation (the ISF and later the IFI), on the condition that the burden not become confiscatory, which for a holding tax may require an income-based cap only when the rate is high (Conseil des prélèvements obligatoires, 2018; Conseil constitutionnel, 2012). The threshold is telling: in the ISF case-law a rate of 0.5% was validated without any cap, whereas a rate of 1.8% required one (Conseil des prélèvements obligatoires, 2018). The maximum annual rate proposed here is 0.5%, the very level the Conseil accepted with no cap, so the French standard is comfortably met. It is worth noting that the Conseil constitutionnel also judged that ability to pay may be assessed on wealth ownership rather than income flows (Decision n° 2019-769 QPC), confirming the legitimacy of a wealth tax.

Austria. Austria discontinued its wealth tax in 1993 by an act of government, not of any court, and for reasons of design rather than principle: fear of capital flight, widespread evasion, high administrative cost, and low and declining revenue, compounded by the unequal treatment of grossly under-valued real estate (the same defect that later led the Constitutional Court to strike down the Austrian inheritance tax) (Directorate-General for Taxation and Customs Union (European Commission), 2026).

However, one genuine legal obstacle is specific to Austria: Article 1(1)(2) of the constitutionally entrenched Final Taxation Act (*Endbesteuerungsgesetz*) bars any wealth tax on bank deposits and domestically issued bonds. Overcoming it would require either amending that constitutional law by a two-thirds majority, or granting Member States the option to exempt those asset classes, which in any case make up only a small share of large fortunes.

European law. Two European-level points complete the picture. First, Article 1 of Protocol No. 1 to the European Convention on Human Rights protects the peaceful enjoyment of possessions but explicitly permits States to levy taxes, subject to a “fair balance” between the general interest and the individual burden; the Court finds a violation only where the charge is disproportionate or confiscatory, and a one-off levy of at most 0.5% of wealth per year with an ability-to-pay ceiling sits well within that margin. Second, Article 345 of the Treaty on the Functioning of the European Union provides that “the Treaties shall in no way prejudice the rules in Member States governing the system of property ownership”: EU law is neutral as between private and public ownership, so using the proceeds to build up collective, public ownership of productive capital raises no objection under the Treaties.

The recurring constitutional theme across jurisdictions is that wealth taxes fail when they value assets unequally, tax fictitious returns, or become confiscatory, never simply because they tax wealth. The present design is built to avoid all three failure modes.

5 Possible variants

Several variants are compatible with the architecture above but are left for future work and not developed here: (i) converting the one-off levy into a *permanent* recurrent wealth tax; (ii) applying

higher rates above EUR 100 million wealth, closer to the 2%–3% minimum-tax proposals of [Zucman \(2024\)](#); (iii) pairing the wealth tax with a reform of *inheritance* and *capital gains taxation*, which reaches the same tax base at the point of transmission; and (iv) allocating the revenue to EU own resources rather than to a sovereign wealth fund. Each of these would change the efficiency, legal and political properties of the instrument and deserves separate analysis.
